Exercise 1, Oct 11, 2017

Consider a Braitenberg vehicle number 2, with two sensors, which are connected to the ipsilateral (same side) effector. Assume the sensor characteristic is monotonically *decreasing* while the motor characteristic is monotonically *increasing*.

- 1. Analyze the behavior in the presence of a single source of stimulation by making a drawing and arguing qualitatively. [Reproduce the logic discussed in the lecture.]
- 2. Question this logic by considering the case in which the vehicle drives very fast. What would make the vehicle drive fast? [Think in terms of the sensory and motor characteristics.] If it drove so fast, that it couldn't turn in time before shooting beyond the target. What would happen? By implication, which implicit assumption was made in the lecture?
- 3. What would happen if the sensor characteristic has a zero crossing, e.g., at a positive level of the sensed physical intensity, activation is zero? [With the understanding, that negative activation going into the motor characteristic makes the motor turn backward.] Argue similarly in words, perhaps with a drawing to support the argument.
- 4. What would happen if there were two sources in the environment? Make a drawing of the sensed intensity and distinguish different cases.
- 5. What would it take to transform all this into a more formal, mathematical analysis?
